Coumarin: Chemical and Pharmacological Profile

P. K. Jain and Himanshu Joshi

ABSTRACT

Coumarins are classified as a member of the benzopyrone family, all of which consist of a benzene ring joined to a pyrone ring. The benzopyrones can be subdivided into the benz-alfa-pyrones to which the coumarins belong and the benzo-gama-pyrones, of which the flavonoids are principal members. Umbelliferone, esculetin and scopoletin are the most widespread coumarins in nature. During the synthesis of these compounds ortho-hydroxylation should respectively take place on p-coumaric, caffeic and ferulic acid. The coumarins are of great interest due to their pharmacological properties. In particular, their physiological, bacteriostatic and anti-tumor activity makes these compounds attractive backbone derivatisation and screening as novel therapeutic agents.

Keywords: coumarin, benzopyrone, flavonoids, anti-tumor activity, bacteriostatic

INTRODUCTION

Coumarins owe their class name to ‘Coumarou’, the vernacular name of the tonka bean (Dipteryx odorata Willd, Fabaceae), from which coumarin, it was isolated in 1820 (Bruneton, 1999). There are four main coumarin sub-types: the simple coumarins, furanocoumarins, pyrano-coumarins and the pyrone-substituted coumarins. The simple coumarins (e.g. coumarin, 7-hydroxycoumarin and 6,7-dihydroxycoumarin), are the hydroxylated, alkoxylated and alkylated derivatives of the parent compound, coumarin, along with their glycosides. Furanocoumarins consist of a five-membered furan ring attached to the coumarin nucleus, divided into linear or angular types with substitution at one or both of the remaining benzoid positions (Ojala T., 2001). Pyrano-coumarin members are analogous to the furanocoumarins, but contain a six-membered ring. Coumarins substituted in the pyrone ring include 4-hydroxycoumarin (Keating et al, 1997). The synthetic compound, warfarin, belongs to this coumarin subtype. By virtue of its structural simplicity coumarin has been assigned as head of the benzo-alpha-pyrene, although it is generally accepted that 7-hydroxycoumarin be regarded as the parent compound of the more complex coumarins (Murray et al, 1982). Genistein is an isoflavone and belongs to the benzo-gama-pyrones. It is a natural component of soy and has been intensively investigated as a chemopreventive agent, mainly against hormonally regulated breast and prostate cancers in animal models (Constantinou et al, 1990, Finn et al, 2002).
Coumarins comprise a very large class of compounds found throughout the plant kingdom. They are found at high levels in some essential oils, particularly cinnamon bark oil (7,000 ppm), cassia leaf oil (up to 87,300 ppm) and lavender oil. Coumarin is also found in fruits (e.g. bilberry, cloudberry), green tea and other foods such as chicory (Lake, 1999). Most coumarins occur in higher plants, with the richest sources being the Rutaceae and Umbelliferae. Although distributed throughout all parts of the plant, the coumarins occur at the highest levels in the fruits, followed by the roots, stems and leaves. Environmental conditions and seasonal changes can influence the occurrence in diverse parts of the plant. Recently six new minor coumarins have been isolated from the fruits and the stem bark of Calophyllum dispers (Clusiaceae). The genus Calophyllum, which comprises 200 species, is widely distributed in the tropical rain forest where several species are used in folk medicine (Guilet et al, 2001). Although most of the natural coumarins in existence have been isolated from the higher plants, some members have been discovered in microorganisms. Some important coumarin members have been isolated from microbial sources e.g. novobiocin and coumermycin from Streptomyces, and aflatoxins from Aspergillus species (Cooke et al, 1997, Cooke, 1999).

**Chemical Profile**

**Structure**

Coumarin and its derivatives are principal oral anticoagulants. Coumarin is water insoluble; however 4-hydroxy substitution confers weak acidity to the molecule that makes it water soluble under slightly alkaline conditions.

The structures of coumarin and its derivatives are as shown below. Warfarin is marketed as the sodium salt. It has one chiral center. The S (-) isomer is about 5 - 8 times more potent than the R (+) isomer; however, commercial warfarin is a racemic mixture.

**Structure Activity Relationships**

Coumarin and 4-hydroxycoumarin do not possess anticoagulant activity. Link, who pioneered the isolation and characterization of bis’ hydroxycoumarin (dicoumarol) from sweet clover, concluded that the minimal requirements for anticoagulant activity are 4-hydroxy group, a 3-substituent, and a bis molecule (Chen et al, 2001).
The cis form is very unstable, therefore, will tend to go to the Trans configuration. Glucose is a leaving group which assists in the cis-trans transformation. A specific enzyme found in Melilotus Alba (Leguminosae) specifically hydrolyses the cis-glucoside (beta-glucosidase).

Umbelliferone, esculetin and scopoletin are the most widespread coumarins in nature. Thus this biosynthesis pathway showed that all coumarins oxygenated at position 7 (Desai, 2005, Friedli, 2001).

Pharmacological Profile

Due to its biochemical properties coumarin was proposed for use in clinical medicine, they should be evaluated for the treatment of various clinical conditions.

High Protein edema (HPE)

The lymph system is responsible for drainage of interstitial fluid within human tissues. edema interferes with the metabolism of the tissue cells and reduces oxygen transport, resulting in problematic wound healing. In the case of high protein edemas (HPO), there is an accumulation of protein in the tissue following trauma or inflammation, with resulting permeability of the capillaries causing water leakage in the tissue species (Velasco-Velazquez et al, 2003 ). Many disease states are associated with high protein edemas, ranging from extremely severe and chronic (e.g. lymph edema and elephantiasis) through more common and acute forms (e.g. burns, accidental and surgical traumas). Coumarin and numerous other benzopyrones have been tested in high protein edema, and able to subsidize swelling. However, according to Loprinzi and colleagues, coumarin treatment alone is not effective therapy for women who have lymph edema of the arm after treatment for breast cancer. It may be possible to increase the beneficial therapeutic effect of coumarin by using it with other compounds into main combination treatments (Ebbinghaus et al, 1997). The objective of a recent study was to evaluate the edema-protective effect of a combination vasoactive drug, coumarin/troxerutin (SB-LOT) plus compression stockings in patients suffering from chronic venous insufficiency after decongestion of the legs as recommended by the new guidelines. The study confirms the edema-protective effect of SB-LOT in chronic venous insufficiency and provides a treatment option for patients who discontinue compression after a short time (Vuky et al, 2000).

Chronic Infections

In addition to its stimulatory effect on macrophages, coumarin has been shown to activate other cells of the immune system. In chronic brucellosis Brucella abortis infects macrophages, thus eluding the immune response (Thornes et al, 1982). When immunostimulatory drugs such as coumarin are administered, and the symptoms of chronic brucellosis disappear. These results have encouraged the use of coumarin in other chronic infections such as mononucleosis, mycoplasmosis, toxoplasmosis and Q fever. A new antiplasmodial coumarin has been isolated from the roots of Toddalia asiatica. This finding supports the traditional use of this plant for the treatment of malaria (Dexeus et al, 1990).

Cancer treatment

Anti-cancer drugs have traditionally been targeted to damage the aberrantly dividing cell by interrupting the cell division process. Reagents used include DNA intercalating agents (e.g. Adriamycin), DNA cross-linking agents (e.g.cis-platin), topoisomerase inhibitors (e.g. camptothecins), cytoskeleton-disrupting agents (e.g. vinblastin) and antimetabolites (e.g. mercaptopurine). These drugs are effective, and cytotoxic, and thus exhibit severe side effects, particularly on normal proliferating tissues such as the haematopoietic system (Kokron et al, 1991, Marshall et al, 1991, Bosland, 1991). Often combination therapies, whereby several cytotoxic agents are combined in the treatment regime, offer better results with fewer toxic side-effects, as they are carefully regulated to allow recovery of normal, but not malignant cells, from drug exposure. Currently, chemotherapy, radiotherapy and surgery combined offer the best outcomes for cancer patients and treatment combinations have been successfully applied to particular cancer types, for example, Hodgkin’s lymphoma, testicular cancer and various leukemias. Coumarins can be used not only to treat cancer but to treat the side effects caused by radiotherapy (Agarwal, 2000, Marshall et al, 1990). A recent study
investigated the efficacy of coumarin/troxerutin combination therapy for the protection of salivary glands and mucosa in patients undergoing head and neck radiotherapy. The results suggest that coumarin/troxerutin have a favorable effect in the treatment of radiogenic sialadentitis and mucositis (Mahler et al, 1992). The interest in coumarin and 7-hydroxycoumarin as anti-cancer agents arose from reports that these agents had achieved objective responses in some patients with advanced malignancies (Myers et al, 1994).

**Blood Coagulation and Anticoagulant**

The physiological systems that control blood fluidity are both complex and elegant. Blood must remain fluid within the vasculature and yet clot quickly when exposed to no endothelial surfaces at sites of vascular injury. When intravascular thrombi do occur, a system of fibrinolysis is activated to restore fluidity. A delicate balance prevents both thrombosis and hemorrhages and allows physiological fibrinolysis without excess pathological fibrinogenolysis. The drugs described in this article have very different mechanisms of action, but all alter the balance between procoagulant and anticoagulant reactions. With these drugs, efficacy and toxicity are necessarily intertwined. For example, the desired therapeutic effect of anticoagulation can be offset by the toxic effect of bleeding due to overdosing of anticoagulant. Similarly, overstimulation of fibrinolysis can lead to systemic destruction of Fibrinogen and coagulation factors. The predominant agents for controlling blood fluidity, including arbitrary anticoagulant heparin and its derivatives, which stimulate a natural inhibitor of coagulant proteases. The coumarin as anticoagulants, which block multiple steps in the coagulation cascade. Fibrinolysis agents, which lyse pathological thrombi. Anti platelet agents, especially aspirin. The pathway of clot removal, fibrinolysis, along with sites of action of fibrinolysis agents. Coumarins are competitive inhibitors of vitamin-K in the biosynthesis of prothrombin. The coagulation cascade relies on the conversion of prothrombin to thrombin in a very important step under the condition (Goodman & Gilman’s, 2006).

**Inflammation**

The inflammatory process is the response to an injurious stimulus. It can be evoked by a wide variety of noxious agents (e.g., infections, antibodies, or physical injuries). The ability to mount an inflammatory response is essential for survival in the face of environmental pathogens and injury; in some situations and diseases, the inflammatory response may be exaggerated and sustained without apparent benefit and even with severe adverse consequences. No matter what the initiating stimulus, the classic inflammatory response include warm, pain, redness, swelling. It has been proposed that some, but not all, NSAIDs may interfere with adhesion by inhibiting expression or activity of certain of these cell-adhesion molecules. Novel classes of anti-inflammatory drugs directed against cell-adhesion molecules are under active development but have not yet entered the clinical area. Coumarin and their derivatives are highly effective against inflammatory response (Goodman & Gilman’s, 2006).

**CONCLUSION**

The coumarins are of great interest due to their biological properties. Their physiological, bacteriostatic and anti-tumor activity makes these compounds attractive for further backbone derivatisation and screening as novel therapeutic agents. Weber and co-workers have shown that coumarin and its metabolite 7-hydroxycoumarin have antitumor activity against several human tumor cell lines. Both coumarin and coumarin derivatives have shown promise as potential inhibitors of cellular proliferation in various carcinoma cell lines. In addition it has been shown that 4-hydroxycoumarin and 7-hydroxycoumarin inhibited cell proliferation in a gastric carcinoma cell.
