**ABSTRACT**

The fruit of *Citrullus colocynthis* (L.) Schrad. (Cucurbitaceae) in its dried or fresh forms is consumed by some patients of M’sila region (Algeria) for its antidiabetic, antirheumatic, antihemorrhoids activities without considering its safety. The first step of the study was undertaken to determine the acute median lethal dose of the methanol extract. The objective of the second step was to evaluate the toxic effects of this extract at a single daily oral dose (131 mg/kg) in 50 Albino rats divided into 5 experimental (A, B, C, D and E) and 1 control groups after different period of treatment. Liver, kidney and bone marrow function test were assessed using standard techniques. The acute median lethal dose of the extract was found to be 1311.45 mg/kg. The plasma ALT, AST, urea and creatinine levels were significantly affected, an indication that the extract is hepato-nephrotoxic. The results obtained for hematological parameters reflect that methanol extract with a dose of 131 mg/kg did not affect quantitatively but disrupted qualitatively some functions of the bone marrow. The present study showed that the intake of extract of ripe *Citrullus colocynthis* fruit presented some adverse effects on the functions of the liver, kidney and bone marrow in rats.

**INTRODUCTION**

The Cucurbitaceae plant, *Citrullus colocynthis* is locally known as “Handhal” or “Hdejj”, and prevalent in south Algeria. It is also called Wild Watermelon, Bitter apple, Bitter gourd and Bitter cucumber (Zamani et al., 2007). Colocynth (CCT) contains active substances such as saponins, alkaloids and glycosides (Abdel-Hassan et al., 2000). The main constituents of the plant are highly oxygenated tetracyclic triterpene compounds called cucurbicin (Seger et al., 2005). There are a variety of cucurbicin compounds including cucurbitacin A, B, C, D, E, F, I, L and glucosides (Nayab et al., 2006). Fruit contains α-glucosides colocynth, its aglycone α-elaterin, citrullin, citrullene and citrullic acid. Unripe fruits contain p-hydroxy benzyl ester. Roots contain α-elaterin and herniacontane (Husain et al., 1992). The *Citrullus colocynthis* is well reputed for its therapeutic activity in folklore. The fruits and, in particular, the pulp of this plant are well known natural cathartics since ancient times. The leaves of this herb are used to treat asthma and jaundice, whereas the root is a traditional treatment for amenorrhea, breast inflammation, arthralgias, and ophthalmic diseases. Other medicinal uses include the treatment of seizures, tuberculosis, syphilis, and parasitic infections (Blaskovich et al., 2003). *C. colocynthis* is mostly used by many diabetics in developing countries (Errajra et al., 2010; Ziyyat et al., 1997). Many scientific studies have been undertaken on laboratory animals to show the hypoglycemic effect of this plant (Khalil et al., 2010; Atole et al., 2009). Case reports associate the use of extracts of *Citrullus colocynthis* with the development of bloody diarrhea, vomiting, colicky abdominal pain, and dehydration (AlFaraj, 1995). Pathologic lesions primarily involve edema, erythema, superficial erosions and inflammatory exudates of the mucosa in the sigmoid and descending colon. Ulcerations and pseudopolyps are unusual features of this toxic colitis. Symptoms typically resolve within 3-6 days, and the pathological lesions resolve within 14 days without sequelae. There are few data on the dose response of the toxin in colocynth, in part because of the lack of identification of the specific compound associated with the toxic colitis.
The older medical literature suggests that 0.6-1 g of colocynth extract can produce bloody diarrhea (Goldfain et al., 1989). The objective of this study is to evaluate the acute toxicity of the fruit extract of C. colocynthis on liver and kidney of male rats Wistar Albino.

MATERIAL AND METHODS

Plant material

Citrullus colocynthis (CCT) plant were collected during August and September from the desert area of Maârif (35.5°W and 5.25°N) in province of Boussaâda, Wilaya of M’sila, Algeria. The plant was identified, authenticated by Botanist Pr. H. Laouer, Department of Biology, Ferhat Abbas University, Setif, Algeria. Fruits were washed and shade dried. Seeds were separated manually from the pulp of the fruits and then minced with electrical grinder (Muleinex) into a powder and finally stored in airtight containers prior to use (Fig. 1, 2).

Preparation of the methanol extract of the fruit of Citrullus colocynthis

Hundred grams of Air dried powdered of fruits were extracted to exhaustion with 600 ml methanol, using a soxhlet apparatus for 18 h. The resulting extracts were evaporated at reduced pressure to obtain crude extract. The yield of this extract was approximately 13.73± 0.02% (w/w).

Experimental animals

Male Albino-Wistar rats weighing between 180 to 210 g were obtained from animal center of Pasteur’s Institute (Algiers – Algeria). Rats were housed in hanging transparent plastic cages (55 × 33× 19 cm) in the animal room of Faculty of Sciences University Ferhat Abbas Setif Algeria and acclimated for 3 weeks prior to experiment. The litter was renewed every 3 days. They were fed with a standard pellet and tap water ad libitum. All animals were kept in standard environmental conditions. Each rat was identified by body marks using 1% picric acid solution. All experimental procedures were conducted in accordance with the guide for care and use of laboratory animals and in accordance with the scientific council of the Faculty of Natural Sciences and Life of the University Ferhat Abbas, Sétif – Algeria.

Acute toxicity studies in male rat.

Determination of LD₅₀

The fruit extract of Citrullus colocynthis to be tested is dissolved in a few drops of methanol and diluted in saline and administered at different doses, by gavage at a dose per group. Male rats were weighed 186.25 ±2.80 g, identified by labeling with an aqueous solution of picric acid and divided into groups of 10 animals each and fasting for short period before oral administration of single doses of the fruit-extract of Citrullus colocynthis. Five groups of rats are treated with simple application and successively with the following doses: 500, 1000, 1800, 2000 and 3000 mg/kg. The control group received physiological saline with a few drops of alcohol. After administration of the extract of fruits, animals were observed individually every hour during the first day and every day for 14 days. Behavior and clinical symptoms of animals are noted throughout the duration of the experiment. LD₅₀ and its range are calculated by the graphic method of Litchfield and Wilcoxon (1949).

Acute toxicity in male rats.

The rats were divided in random into 5 groups, each of 10 rats. Four groups received per os 131 mg/kg (=1/10 DL₅₀) of the methanolic extract of fruit pulp of Citrullus colocynthis but were killed after 24 hours, 5 days, 10 days and 14 days of the treatment. One group was maintained as normal control and received normal saline. At the end of all experimental periods, animals were anaesthetized with urethane at the dose 760 mg/kg. Two kinds of blood were obtained from the retro-orbital vein, a sample for hematology containing ethylene diamine tetraacetic acid for measurement (Erythrocyte (RBC) and leukocyte (WBC).
counts, hemoglobin concentration (Hb), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), mean platelet volume (MPV) and platelets hematocrit (PCT) with apparatus MEDONIC (Beckman Coulter – USA) and sample for serum and used for measurement of activities Glutamic-oxaloacetic transaminase (GOT), Glutamic- Pyruvic Transaminase (GPT) (using commercial Kits – SGM Rome-Italy), alkaline phosphatase (ALP) (using commercial Kits – CYPRESS DIAGNOSTIC Langdrop – Belgium), concentrations of total protein, urea, glucose, creatinine, sodium, potassium, calcium and phosphorus with apparatus TECHNICON RA-1000-USA. After blood collection, the animals were sacrificed by cervical dislocation. After autopsy, all tissues were examined grossly and major’s organs (liver, brain, heart, kidneys, spleen, testes and lung) were weighted. The relative organ weight (weight of organ as a proportion of the total weight of each rat) was calculated and compared with the value of the control

Statistical analysis
The t-test and a probability level of $P < 0.05$ were chosen as the criteria for statistical significance. Values reported are mean ± standard error of the mean (SEM). The median lethal dose $LD_{50}$ was determined according to Litchfield and Wilcoxon method (1949).

RESULTS
The Median lethal dose
The animals were kept under observation for 72 hours after dosing to check for symptoms, behavioral changes and death. The doses tested produced, early within the first few hours of treatment the following signs which worsens with the passing of the time: lose of locomotion activity, ataxia, and at the highest doses administered, lethargy, hypothermia and death. Severe diarrhea was the most serious symptoms; after developing it, all the experimental animals died.

The animals that survived had some symptoms, including mild diarrhea, but were able to recover. The intensity of the toxic effects was dose-dependent. Rats mortality after different doses of CCT methanol extract was plotted against probability values (Litchfield and Wilcoxon, 1949). The mortality rate in male rats was maximum (100%) in groups treated with 3000 mg/kg.

The acute median lethal dose ($LD_{50}$) of the extract was found to be respectively 1311,45 mg/kg (at 95% confidence limit of (1037,80 to 1657,27 mg/kg) for male rats. The $LD_{50}$ and $LD_{95}$ were respectively 825,61 mg/Kg and 2083,19 mg/Kg (Fig. 3).

Acute toxicity in male rats
The main signs of toxicity observed after oral administration of single dose tested (131 mg/kg ≈ 1/10 $LD_{50}$) were: diarrhea, ruffled hair, acceleration of heart rate, breathing difficulty, soft feces and huddling together. None of the rats in all treated groups died during the course of the experiment.

There were no statistically significant differences in average body weight of the control group and Citrullus colocynthis fruit-extract treated groups during the acute toxicity. But significant differences were detected in the weight gain of male rats treated C.C fruit extract, as compared to control group (Table. 1). Macroscopic examination of various organs in situ did not show any morphological changes in organs of treated animals compared with those of control rats.

No significant changes were noted on the relative weights of liver, brain, kidney and testes among the treated groups. But the group sacrificed after 10 days of treatment has presented a significant reduction in the relative weights of the kidney, lungs, heart and spleen compared to control group (Table 2).

The hematological parameters of rats treated with Citrullus colocynthis-extract are presented in table 3. The RBC (red blood cells), HCT (hematocrit), HGB (hemoglobin) and WBC (White blood cells) were higher in the treated groups than control group. The major hematological parameters returned to normal after the 14th days.

The results of the indices of liver function AST (GOT) (glutamic-oxaloacetic transaminase), ALT (GPT) (glutamic-pyruvic) and ALP (alkaline phosphatase) and TP (total protein) are given in table 4. It was observed that the values of GOT and GPT on Day 1 and 5 were significantly higher compared to control. ALP activity was significantly higher in treated groups, sacrificed after 10 and 14 days of application. TP estimation of the acute toxicity revealed significant differences in the most treated groups compared to control (Table-4).

Effect of CC-fruit-extract on kidney function parameters (Table-5) shows the mean kidney function values of the rats treated with CC-fruit-Extract. From the table urea, creatinine and potassium levels were significantly increased in groups A, C, and D when compared with the control.

Calcium was significantly higher in groups A, B and C. no significant variation were obtained in the serum sodium and glucose tested when compared with control.

**DISCUSSION**

*Citrus colocynthis* find wide-spread use in folkloric medicine for treatment of various disorders (Nmila et al., 2000; Adam et al., 2001; Tannin-Spitz et al., 2007; Kumar et al., 2008). *C. colocynthis* is mostly used by many diabetics in developing countries (Errajraji et al., 2010; Ziyat et al., 1997). Theirs toxicoses in grazing animals have been suspected by livestock owners especially at time of drought (Adam et al., 2001). The fruits and leaves of this plant contain cucurbitacins A, B, C, and D and α-elaterin and probably other constituents (Nayab et al., 2006; Bahriet, 1995). The clinical picture of male rats treated with the extract of the fruit of *C. colocynthis*, was characterized by relatively rapid appearance of symptoms, probably due to the rapid absorption of the active principles present in the fruit extract of the plant. Severe diarrhea was the most serious symptom; after developing it, all the experimental animals died. The animals that survived had some symptoms, including mild diarrhea, but were able to recover. The component(s) of the fruit plant extract responsible for the toxic manifestations after the oral dose are not known. The toxicity and lethality of the fruit-extract may be due to any one or more of the phytochemicals present in the crude methanol extract, some of which have been isolated and identified (Abdel-Hassan et al., 2000; Adam et al., 2001; Chen et al., 2005; Delazar et al., 2006; Yoshikawa et al., 2007). This may be
attributed to the effect of saponin and other constituents of *C. colocynthis*, which, was been known to be a strong laxative since antiquity. This is in agreement with the scientific data of Diwan et al. (2000); Bakhiet (1995) and Soulier (1891). The LD₅₀ in male rats is 1311.45 mg/kg. Given the results of the LD₅₀ (500mg/kg <LD₅₀<5000mg/kg), the fruit extract of *C. colocynthis* is classified as moderately toxic products as classified by Loomis and Hayes (1996) and Pascoe (1983). In this study, lethal effect started manifesting from 1000mg/kg for male rats. The lethal effect of the plant can be attributed to an increase in blood pressure and/or cardiac arrhythmias (Wasfi, 1994).

Therefore, the LD₅₀ of 1311.45 mg/kg of the extract is an indication that the extract is not completely safe. However, LD₅₀ has not been regarded as a biological constant because many variables such as animals’ species and strain, age, gender, diet, bedding, ambient temperature, caging conditions and time of the day can all affect the LD₅₀ value obtained; hence there are considerable uncertainties in extrapolating LD₅₀ value obtained for specie to other species. Consequently, recognizing LD₅₀ test as providing, at best, only a ball park estimate of human lethality has been advocated (Zbinden and Flury-Roversi, 1981).

In the acute toxicity in male rats given C.C.fruit extract orally at dose 131 mg/kg, there were no changes in animal behavior, but the body weight gains were significantly different in the treated rats as compared to the control. Since, the changes in body weight have been used as an indicator of adverse effects of drugs and chemicals (El Hilaly et al., 2004). The present results suggest that at the oral dose, the C.C.fruit extract is not completely safe. The present study was designed to evaluate the effects of methanol extract of *C. colocynthis* fruit on the liver and kidney of male rats. Liver and kidney are two important organs that perform vital function for the healthy survival of the body. The liver is known to be a key organ in the metabolism and detoxification of xenobiotic, is vulnerable to damage induced by a huge variety of chemicals as reported by Udem et al., 2009.

An obvious sign of hepatic injury is leakage of cellular enzyme into plasma. When the liver cell membrane is damaged, a variety of enzymes normally located in the cytosol are released into blood stream. The estimation of the GPT (glutamic-pyruvic transaminase) and GOT (glutamic- oxaloacetic transaminase) in the serum is useful quantitative marker for the extent and type of hepatocellular damage (Udem et al., 2009; Kumar et al., 2004). An increase in the level of ALP (Alkaline phosphatase) is an indication of biliary obstruction (Udem et al., 2009; Kaneko et al., 1997). The male rats treated with 131 mg/kg of the methanol fruit extract of *C. colocynthis* showed changes in the level of these enzymes after the 1ˢᵗ, 5ᵗʰ, 10ʰ and 14ᵈ days of the treatment. The level of ALP showed significant increase in groups C and D. However, rats in Group A and B showed a significant increase in GOT and GPT activity until the 5ʰ day. The maximum acute liver toxicity is expressed at day 5 (Szymanowicz and Danel, 2005). The significant increase in serum GPT activity that was observed in the groups A and B could be an evidence of hepatotoxicity caused by the extract. This result is in agreement with the work reported by Khatibi (2012), Dehghani and Pananjehshahin (2006) and Diwan et al. (2000) in mice.

Furthermore, the elevated serum protein concentration in rats treated with the CCT might be interpreted as a result of dehydration arising from fluid loss during diarrhea. The results obtained showed no change of glycaemia in treated rats, this result is in line with the work reported by Benmehdi et al. (2011), who tested the effect of saponoids crude extract isolated from *Citrullus colocynthis* seeds on blood glucose level in rats.

The kidney helps in maintaining homeostasis of the body by reabsorbing important materials and excreting waste products. There was significant difference in the serum levels of urea, creatinine and potassium of the treated animals. Urea is the main end product of protein catabolism and is excreted through urine. Renal diseases which diminish the glomerular filtration lead to urea retention. Creatinine is a waste product formed in muscle by creatine metabolism. Its retention in the blood is evidence of kidney impairment (Wurochekke et al., 2008).

Hematological analysis of plant extract in animals is one of the important methods of assessing the toxicity of plant extract in animals (Ashafa et al., 2009). Haematological studies showed no significant changes in red blood cells and white blood cells after the 1ˢᵗ, 5ᵗʰ, 10ʰ and 14ᵈ days of the treatment. But, the RBC, HCT and HGB were highly increased after the 5ᵗʰ day. In those animals, the increased RBC, HGB and HTC was probably due to haemoconcentration arising from fluid loss resulting from profuse diarrhea that developed in the treated animals. This is consistent with the work of Adam et al. (2001) on sheep.

**CONCLUSION**

It can be concluded that fruit extract of *C. colocynthis* is hepatotoxic and has a toxic effect on the kidney. Effort must be exerted to identify plants utilized in folk medicine having narrow therapeutic indices as their use is dangerous and should be carefully researched, especially plants used by diabetic patients.

**ACKNOWLEDGEMENTS**
