INTRODUCTION

Local people throughout the world have been using medicinal plants to maintain their well-being since time immemorial (Fabricant and Farnsworth, 2001; Falah and Hadiwibowo, 2017; Lulekal et al., 2013; Manzo et al., 2017; Saive et al., 2018; Yazdanshenas et al., 2016). Traditional medicines have also been the fundamental source of modern medicine, drug discovery, and synthesis (Qasim et al., 2014; Stanley et al., 2014). Traditional medicines are considered to be highly effective in the treatment of assorted illnesses (Rokaya et al., 2014). Up to date, more than 70% of people in the third world countries use traditional medicines as an alternative to primary health care (Chen et al., 2016; Kayani et al., 2014; Mahomoodally, 2013; Maroyi, 2011; Mazid et al., 2012; Scott et al., 2004; Sigidi et al., 2016). According to Mander et al. (2007), about 27 million native South Africans still rely upon traditional medicines for treating a range of health problems. Among the utilized species, there are taxa that are threatened with extinction due to overharvesting and habitat destruction (Harisha and Padmavathy, 2013; Kala and Sajwan, 2007). The habit of using threatened medicinal plant species by both village and city communities countrywide and across the globe continues despite the available legal implications set to restrict their collection (Kala, 2005; Ndhlala et al., 2011; Zschocke et al., 2000). Regardless of the availability and accessibility of modern medicines countrywide and worldwide (Seshathri, 2012), a large number of dwellers in the Soutpansberg Region continues to rely on and habitually
preferred the use of herbal medicines without considering their conservation status. The high demand of plant resources due to their medicinal properties has been a major cause of threatened species decline (Van Andel et al., 2015; Williams et al., 2013; Yao et al., 2012), including the species belonging to genus Asparagus L. (Asparagaceae).

It is evident that many species within the genus, Asparagus are being used for medicinal or ornamentals (Goyal et al., 2003; Norup et al., 2015), and they are also listed as either Endangered, Vulnerable, or Near Threatened (Raimondo et al., 2009). The genus Asparagus L. is considered to have more than 200 species distributed within the arid and semi-arid zones worldwide (Fukada et al., 2005; Kubota et al., 2012). About 120 species, including Asparagus sekukuniensis have been recorded in Southern Africa, Europe, and Asia (Batchelor and Scott, 2006; Fellingham and Meyer, 1995). Asparagus sekukuniensis is endemic to the Limpopo province, South Africa and categorized as Endangered as its habitat is widely transformed and degraded due to mining, new settlement development, over-grazing, crop cultivation, and over-collection as an herbal medicine (Burrows et al., 2012; Mukhopadhyay and Ray, 2013). However, there is a scant of literature on the diseases cured by the species, parts used, dosage, and how this species is administered in the traditional health care systems. Therefore, this study aimed at documenting ethnomedicinal uses of A. sekukuniensis, in the Soutpansberg Region, Vhemphe Biosphere Reserve, Limpopo province, South Africa. As like in other aboriginal cultural communities worldwide (Bhat et al., 2013), a large amount of knowledge about the medicinal use of A. sekukuniensis in Soutpansberg’s traditional health care systems is transmitted orally and this wealth of knowledge need to be documented to avoid its subsequent loss. This could not only preserve the Vhavenda’s traditional health care systems and knowledge but also provide baseline data needed for advanced research on the species.

**MATERIALS AND METHODS**

**Study site description**

The current investigation was conducted in four sub-villages of a Vhulaudzi village in Soutpansberg East, Vhembhe Biosphere Reserve, Limpopo province, South Africa (Fig. 1 and Table 1). Study sites were located within the north-eastern region of the Makhado Local Municipality, along the Witflog road to Tshikombani which diverge from N1 north route at approximately 3.5 km from Louis Trichard Makhodo (Fig. 1 and Table 1). The study sites covered the combined surface area of roughly 6.99 km², with the combined estimated population size of 8 276 people (Census, 2011). The study sites are predominantly occupied by the black ethnic group of Vhavenda tribe, who also speak Tshivenḓa as their native language. Vegetation type of study sites is considered to be savanna bushveld (Luseba and Tshisikhawe, 2013). Climatically, the study sites are described by a warm-wet summer (span from October to April) and cold-dry winter (May to September) (Edokpayi et al., 2016; Gumbo et al., 2016; Kephe et al., 2016), with an average annual rainfall range from 300 mm (winter season) to 820 mm (Summer season) (Mpandeli, 2014), and the average annual temperature range from 20ºC during the winter season and 30ºC in summer (Mzezewa and Rensburg, 2011). The topography and geological features of the study sites include Bushveld Igneas complexity, Karoo systems, Limpopo Belt Archaean Cratons, Kalahari Cratons, and the Wylies Poort geological formation of the Soutpansberg Group (Barton et al., 2006; Mostert et al., 2008).

**Ethnobotanical data collection and analysis**

Ethnobotanical data about the medicinal uses and administration of A. sekukuniensis in the treatment of various ailments were gathered from May to December 2018, with an aid of semi-structured dialogues with participants. A total number of 125 participants were arbitrarily chosen, and prior signed informed consent permitted by the University of Fort Hare Research Ethic Committee (Reference no. MAR031RSM01) was obtained from all of them. Among the participants, 44 were laypeople (35.2%), 18 were subsistence farmers (14.4%), and the combined total of 63 specialists were herbal-healers (50.4%) (Fig. 2). Among specialist herbal healers, there was 37 child health-care healer (29.6%), 14 wound healers (11.2%), and 12 general healers (9.6%) (Fig. 2). To intensify the participation confident and smooth flow of ideas amongst the interviewees, face-to-face dialogues were carried-out together with all the participants, at the individual level, using their own local language (Tshivenḓa). To maintain the high-level standard of legitimacy, accuracy and validity of the given answers during the interview sessions, equivalent questions were administered to all the participants of this study. Gathered data were kept in a Microsoft Office spreadsheet program and later analyzed using

ponents of the descriptive statistic, such as frequency of occurrence and fidelity level (FL) (%). FLs (%) were determined using the following formula: FL (%) = \( \frac{N}{n} \times 100 \), where FL (%) is the FL percentage; \( N \) the number of individuals who cited a certain use, and \( n \) is a total number of individuals who cited all the uses (Al-Qura’an, 2009; Umair et al., 2017). Since all participants have cited ethnomedicinal uses of \( A. \) sekukuniensis, \( N \) was equal to 125.

**Plant identification and specimen collection**

Gathered data were supplemented by field inspection walks together with participants for plant identification purposes and specimen collection. The voucher specimen collection permit (ZA/LP/92932) was granted by the Limpopo Department of Economic Development, Environment and Tourism. During the field inspection walk, participants have identified the plant species of interest using its vernacular name and sample specimen was then collected, prepared (pressed and dried), and numbered (RAMLJ 013). A voucher specimen was then deposited at the Botany Herbarium, Life Science and Chemistry Building, the University of Venda for further identification by taxonomists.

**RESULTS AND DISCUSSION**

**Ethnomedicinal uses**

Table 2 reports on the recorded ethnomedicinal uses, preparation techniques, and administration procedures of \( A. \) sekukuniensis by the Vhavenda people in the Soutpansberg Region, Vhembe Biosphere Reserve, Limpopo province, South Africa. A total of six ethnomedicinal uses of \( A. \) sekukuniensis were recorded in this study. FL of the six recorded uses ranged from 8.0% to 24.8% (Table 2). More than 64.8% of all the participants in the current study seemed to be communally utilizing \( A. \) sekukuniensis for child health care-related ailments (Table 2). According to the participants, ensuring child’s health was always an important cultural norm for Vhavenda people in the region and therefore, all newly born infants undergo traditional vaccination rituals to strengthen their immune systems called muthuso (personal communication with the participants). According to Rikhotso (2016), muthuso referred to the use of varied herbal medicines to protect the infants against miscellaneous ailments. The communal use of certain medicinal plant species by various herbal healers proves the effectiveness and therapeutic reliability of these implicated species (Semenya and Maroyi, 2018). Participants across the study sites have stated that they utilized \( A. \) sekukuniensis for curing the variety of ailments, including enhancement of fontanelle closure in infants (FL = 24.8%), convulsions in infants (FL = 22.4%), vaccinating epilepsy in infants (FL = 17.6%), treating the unhealed or cancer-related wounds (FL = 15.2%), genital wounds (FL = 12.0%), as well as boils treatment in both human beings and livestock (FL = 8.0%) (Table 1). Thus, this study argued that the repetitive use of \( A. \) sekukuniensis in addressing miscellaneous ailments (Table 2) demonstrates the variety of biological activities it may possess. The aforementioned statement was supported by other scholars worldwide (Cheikhyoussef et al., 2011; Khan et al., 2014; Mohajedi et al., 2014). However, Jamila and Mostafa (2014) argued that the reliability of traditional herbal medicines, in the treatment and prevention of certain ailment, should not be doubted, but phytochemical validated for authenticity.

The utilized parts of \( A. \) sekukuniensis included roots (50%) and whole plant (50%) (Table 2). The equal utilization proportions of \( A. \) sekukuniensis parts were influenced by the fact that healers do not want to lose any materials of this species since this plant is scanty to be found (personal communication). This was endorsed by the study done by Burrows et al. (2016), whereby \( A. \) sekukuniensis was categorized as an Endangered species under the International Union for Conservation of Nature. Furthermore, this study argued that the equal utilization of \( A. \) sekukuniensis parts demonstrates the equal therapeutic efficacy (Ramarumo et al., 2019). Moreover, the results of this study do not conform to other ethnomedicinal studies in the region since leave was portrayed as the most frequently used plant part (Luseba and Tshipikhaawe, 2013; Mahwasane et al., 2013; Maseve et al., 2015; Mulaudzi et al., 2012).

**CONCLUSION**

The current study has enlightened five uses associated with \( A. \) sekukuniensis which were never reported elsewhere in the world (Table 2). \( A. \) sekukuniensis appeared to be an important herbal medicine against infant ailments, wounds, infections, and infestations. These findings, therefore, call for the evaluation of the phytochemical and pharmacological properties of this species.

**ACKNOWLEDGMENTS**

The current study was sponsored by the National Research Foundation (NRF) of South Africa, the University of Fort Hare (NRF Grant No. 112976). The authors would like to direct their gratitude to Ms Beyi Florence Sekgobela (The traditional healer) together with other participants for their outstanding knowledge sharing and specimen collection.

**CONFLICT OF INTERESTS**

The authors declare that they have no conflicts of interest.

**ETHICAL APPROVAL**

The ethical authorization of this study was permitted by the University of Fort Hare’s Research Ethic Committee (Reference no. MAR031SRAM01).

**FINANCIAL SUPPORT**

This study was sponsored by the National Research Foundation (NRF) of South Africa and the University of Fort Hare (NRF Grand number: 112976).
